

Inferring regulatory networks from microarray data

Lecture 3

Claudio Altafini

SISSA

<http://people.sissa.it/~altafini>

Claudio Altafini, February 14, 2007

– p. 1/60

The “reverse engineering” paradigm

Reverse engineering

Association networks

Linear ODEs networks

task:

method:

- **measured signals:** [mRNA], [proteins] [metabolites]
 - ◆ global response: measure the entire “state” vector
 - time series (e.g. cell cycle)
 - single time point (e.g. steady state)
- **perturbations:** experimental interventions that alter the state of interest

Claudio Altafini, February 14, 2007

– p. 2/60

Network inference algorithms

Reverse engineering

Association networks

Linear ODEs networks

■ a few methods

1. BAYESIAN NETWORK

- ◆ attains a probabilistic graph through a bayesian learning
- ◆ (exact) complexity: superexponential

2. ASSOCIATION NETWORKS

- ◆ learns a graph through a “similarity measure”
- ◆ polynomial complexity

3. LINEAR ODEs MODELS

- ◆ linear complexity
- ◆ suffers from underdetermination
- ◆ model-dependent

- other methods (not discussed): boolean, automata & formal languages, PDEs, stochastic master eq. etc....

Reverse engineering

Association networks

Linear ODEs networks

Association networks

Association networks: similarity measures

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- —NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- given n genes X_1, \dots, X_n
 - given a set of m expression profiles
 - compute a **similarity measure** between the genes
 - associate through edges in a graph genes with the highest similarity measure
 - which similarity measure?
1. **Pearson correlation** of X_i and X_j

$$R(X_i, X_j) = \frac{\sum_{\ell=1}^m (x_i(\ell) - \bar{x}_i)(x_j(\ell) - \bar{x}_j)}{(n-1)\sqrt{v_i v_j}} \in [-1, 1]$$

- linear
 - variants: Spearman correlation (for the ranks \implies non-parametric)
2. Mutual information

Mutual information

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- —NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- X_i = discrete random variable with alphabet \mathcal{A}
- Shannon entropy

$$H(X_i) = - \sum_{\phi \in \mathcal{A}} p(\phi) \log p(\phi), \quad \text{where } p(\phi) = Pr(X_i = \phi), \quad \phi \in \mathcal{A}$$

- joint entropy of X_i, X_j

$$H(X_i, X_j) = - \sum_{\phi, \psi \in \mathcal{A}} p(\phi, \psi) \log p(\phi, \psi)$$

- **Mutual information** of X_i and X_j

$$I(X_i; X_j) = \sum_{\phi, \psi \in \mathcal{A}} p(\phi, \psi) \log \frac{p(\phi, \psi)}{p(\phi)p(\psi)} \geq 0$$

- when the joint probability factorizes, the MI vanishes

$$p(\phi, \psi) = p(\phi)p(\psi) \implies I(X_i; X_j) = 0.$$

Conditioned similarity measures

● Reverse engineering

Association networks

● Pearson Correlation

● Mutual information

● Partial Pearson correlation

● Conditional mutual information

● Higher order conditioning

● Algorithms evaluation

● ARACNe: the algorithm

● Data available

● Results

● MYC subnetwork

● Discussion & Limitations

Linear ODEs networks

- both $R(X_i, X_j)$ and $I(X_i; X_j)$ cannot distinguish between direct and indirect interactions
- \implies graph constructed will have *many* false positives
- **indirect interactions:** $\exists X_k$ that explains all the correlation between X_i and X_j ?

if “yes” then extract the information due to X_k by means of conditioning

Partial Pearson correlation

● Reverse engineering

Association networks

● Pearson Correlation

● Mutual information

● Partial Pearson correlation

● Conditional mutual information

● Higher order conditioning

● Algorithms evaluation

● NETWORKS FOR HUMAN B CELLS

● ARACNe: the algorithm

● Data available

● Results

● MYC subnetwork

● Discussion & Limitations

Linear ODEs networks

- **1st order partial Pearson correlation**

$$R(X_i, X_j | X_k) = \frac{R(X_i, X_j) - R(X_i, X_k)R(X_j, X_k)}{\sqrt{(1 - R^2(X_i, X_k))(1 - R^2(X_j, X_k))}} \in [-1, 1]$$

- take the minimum w.r.t all X_k

$$R_{C_1}(X_i, X_j) = \min_{k \neq i, j} |R(X_i, X_j | X_k)|$$

- if $R_{C_1}(X_i, X_j) \simeq 0$
 - $\implies \exists k$ s.t. X_i and X_j are conditionally independent
 - \implies Markov triple $X_i \longleftrightarrow X_k \longleftrightarrow X_j$
 - \implies no edge between X_i and X_j in the graph

Conditional mutual information

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- **Conditional mutual information**
- Higher order conditioning
- Algorithms evaluation
- —NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- conditional entropy of X_j given X_i

$$H(X_j | X_i) = H(X_i, X_j) - H(X_i)$$

- **conditional mutual information** given X_k

$$I(X_i; X_j | X_k) = H(X_i | X_k) - H(X_i | X_j, X_k) \geq 0$$

- take the minimum w.r.t all X_k

$$I_C(X_i; X_j) = \min_{k \neq i, j} I(X_i; X_j | X_k)$$

- if $I_C(X_i; X_j) \simeq 0$
 - $\implies \exists k$ s.t. X_i and X_j are conditionally independent
 - \implies Markov triple $X_i \longleftrightarrow X_k \longleftrightarrow X_j$
 - \implies no edge between X_i and X_j in the graph

Association networks v.s. Bayesian networks

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- **Conditional mutual information**
- Higher order conditioning
- Algorithms evaluation
- —NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- Bayesian network *structure inference* problem: try to learn the positions of the edges on a graph

- ◆ exponential complexity
- ◆ looks for “true” dependences

- Association networks: guarantees that some edges are missing

- ◆ $R(X_i, X_j) \simeq 0 \implies X_i$ and X_j independent
- ◆ $R((X_i, X_j) \neq 0 \not\Rightarrow X_i$ and X_j linked, since $R(X_i, X_j | X_k)$ could be $\simeq 0$
- ◆ \implies guarantees only independencies
- ◆ polynomial complexity $R \in O(n^2)$, $R_{C_1} \in O(n^3)$

Higher order conditioning

● Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- Even if $R(X_i, X_j | X_k)$ is high, it could be $R(X_i, X_j | X_k, X_\ell) \simeq 0$

- $\implies X_k$ and X_ℓ “explain” all the correlation between X_i and X_j
- if I could condition over $n - 2$ variables: “true” independent correlation between X_i and X_j
- complication: $O(n^n)$ untreatable

Graphical Gaussian modeling

● Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- theory of “Graphical modeling”
D. Edwards “Introduction to graphical modelling”, Springer, 2000
- given R
- $\Omega(\omega_{ij}) = R^{-1} =$ concentration matrix
- true partial correlation

$$R_{C_{\text{all}}}(X_i, X_j) = -\frac{\omega_{ij}}{\sqrt{\omega_{ii}\omega_{jj}}}$$

- $R_{C_{\text{all}}}(X_i, X_j)$ high $\implies X_i$ and X_j are linked
- complication: $m < n$ (n. of experiments < n. of genes)
- $\implies R$ is normally not full rank
- \implies generalized inverses (ill-conditioned)

Algorithms evaluation

● Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning

● Algorithms evaluation

- NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- to evaluate the power of the algorithms: → artificial network
 - ◆ known graph (→ adjacency matrix A)
 - ◆ synthetic data as “gene profiles”

$$A = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 \end{bmatrix}$$

$$\frac{dx_i}{dt} = V_i \prod_{j=j_1}^{j_a} \frac{x_j^\nu}{x_j^\nu + \theta_{ij}^\nu} \prod_{k=k_1}^{k_b} \frac{\theta_{ik}^\nu}{x_k^\nu + \theta_{ik}^\nu} - \lambda_i x_i$$

Algorithms evaluation

● Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning

● Algorithms evaluation

- NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- for each algorithm:
 - ◆ **Input:** true connectivity matrix A_{true}
 - ◆ **Output:** matrix of edges weight W
 - ◆ \implies reconstructed adjacency matrix $\hat{A} = W > w_o$

- parameters

TP (true positives)	=	correctly identified true edges
FP (false positives)	=	spurious edges
TN (true negatives)	=	correctly identified zero edges
FN (false negatives)	=	not recognized true edges

- $\text{edges}(A_{\text{true}}) = TP + FN, \quad \text{edges}(\hat{A}) = TP + FP$
- $\text{zeros}(A_{\text{true}}) = FP + TN, \quad \text{zeros}(\hat{A}) = FN + TN$

Algorithms evaluation

recall (or sensitivity)	true positive rates	$= \frac{TP}{TP+FN} = \frac{TP}{\text{edges}(A_{\text{true}})}$
specificity	true negative rates	$= \frac{TN}{TN+FP} = \frac{TN}{\text{zeros}(A_{\text{true}})}$
precision	positive predicted values	$= \frac{TP}{TP+FP} = \frac{TP}{\text{edges}(\hat{A})}$

Linear ODEs networks

K. Basso, A. A. Margolin, G. Stolovitzky, U. Klein, R. Dalla-Favera, A. Califano. *Reverse engineering of regulatory networks in human B cells*, Nature Genetics 37, 382 - 390 (2005)

- goal: network reverse engineering in mammalian cells (here human B cells) as a key in understanding cell physiology and disease
- challenges of mammalian networks:
 - ◆ integrative approaches are not yet fully applicable given the very scattered nature of the available mammalian cell information
 - ◆ e.g.: systematic (experimental) gene perturbations are technically challenging and time-consuming

Regulatory networks in human B cells

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning

● NETWORKS FOR HUMAN B CELLS

- ARACNe: the algorithm
- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- algorithm used ARACNe (algorithm for the reconstruction of accurate cellular networks)
 - ◆ identifies statistically significant gene-gene coregulation by mutual information
 - ◆ eliminates indirect relationships, in which two genes are coregulated through one or more intermediaries, by means of the 'data processing inequality' (from transmission theory)
 - ◆ \implies relationships included in the network with high probability represent
 - direct regulatory interactions
 - interactions mediated by post-transcriptional modifiers (undetected from gene-expression profiles)
 - algorithm complexity: $O(n^3) \implies$ allows to analyze large scale networks

ARACNe: the algorithm

Linear ODEs networks

A A. Margolin, I Nemenman, K Basso, U Klein, C Wiggins, G Stolovitzky, R Dalla Favera, A Califano *ARACNE: An Algorithm for the Reconstruction of Gene Regulatory Networks in a Mammalian Cellular Context*, BCM Bioinformatics, 2006

- assumption: static inter-gene statistical dependencies only
- joint probability distribution

$$P(\{X_i\}) = \frac{1}{Z} \exp \left[-\sum_i \Phi_i(X_i) - \sum_{i,j} \Phi_{i,j}(X_i, X_j) - \sum_{i,j,k} \Phi_{i,j,k}(X_i, X_j, X_k) - \dots \right]$$

$$= \frac{1}{Z} \exp [-\mathcal{H}(\{X_i\})]$$

where

- ◆ $n = \#$ of genes,
- ◆ $m = \#$ of samples,
- ◆ $Z =$ partition function
- ◆ $\Phi_i(X_i) =$ potentials
- ◆ $\mathcal{H}(\{X_i\}) =$ Hamiltonian

ARACNe: the algorithm

Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- NETWORKS FOR HUMAN B CELLS

ARACNe: the algorithm

- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- simplest possible model: all genes are independent

$$\mathcal{H}(\{X_i\}) = \sum_i \Phi_i(X_i)$$

- next: pairwise interactions

$$\mathcal{H}(\{X_i\}) = \sum_i \Phi_i(X_i) - \sum_{i,j} \Phi_{i,j}(X_i, X_j)$$

→ we take this truncation as our “joint”

- statistical independent vs non-interacting genes

- ◆ X_i, X_j **statistically independent** if

$$P(X_i, X_j) \simeq P(X_i)P(X_j)$$

- ◆ X_i, X_j **non-interacting** if $\Phi_{ij}(X_i, X_j) \simeq 0$

“statistical independent” \Rightarrow “non-interacting”
 \Leftarrow

$$\left(P(X_i, X_j) \simeq P(X_i)P(X_j) \Rightarrow \Phi_{ij}(X_i, X_j) \simeq 0 \right)$$

- when is this happening?

when there are **indirect interactions!**

ARACNe: the algorithm

- NETWORKS FOR HUMAN B CELLS

ARACNe: the algorithm

- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- testing all potential interactions $\Phi_{ij}(X_i, X_j)$ is computationally heavy and sample demanding \Rightarrow methods to reduce the cost

- step 1: identify candidate interactions by the pairwise *mutual information*

$$I_{ij} = I(X_i, X_j)$$

- ◆ put a threshold:

$$\text{if } I_{ij} \leq I_0 \text{ then } \Phi_{ij} = 0$$

- ◆ → Relevance network approach
- ◆ problem: does not detect indirect interactions
- ◆ i.e., co-regulated genes may have $I_{ij} > I_0$ but still $\Phi_{ij} = 0$

ARACNe: the algorithm

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- NETWORKS FOR HUMAN B CELLS

ARACNe: the algorithm

- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

■ step 2: use the *data processing inequality* (DPI)

- ◆ meaning: if X_1 and X_3 interact only through a third gene, then it must be

$$I(X_1, X_3) \leq \min(I(X_1, X_2), I(X_2, X_3))$$

$\implies \Phi_{13}$ can be removed (indirect interaction)

- ◆ checking all triplets above statistical significance I_{ij}, I_{jk}, I_{ki} the DPI removes the least significant arc

\implies Markov triple $X_1 \longleftrightarrow X_2 \longleftrightarrow X_3$

■ Theorem: if I_{ij} are correct (“asymptotic behavior,” meaning “many data”) and if the network is a tree \implies the ARACNe reconstructs the network exactly

- ◆ meaning of the DPI: interactions decorrelate rather quickly
- ◆ caution: 3-node loops are always opened!
- ◆ algorithm focuses on a network that locally is a tree
- ◆ long loops may survive the “pruning”

Data available

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation

ARACNe: the algorithm

- Data available
- Results
- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

■ ~ 6000 genes

■ 336 gene expression profiles representative of perturbations of B cell phenotypes:

- ◆ **normal cells**: resting pre-germinal center naive B cells, proliferating germinal center B cells (centroblasts and centrocytes) and post-germinal center memory B cells
- ◆ **Transformed cells** more than ten subtypes of B cell malignancies
- ◆ **Experimentally manipulated cells** treated in vitro to induce specific signal transduction pathways or engineered for the expression of several transcription factors

■ organism- and tissue-specific perturbations \implies highly specific interactions

Results

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available

● Results

- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- network of ~ 120.000 interactions
- connectivity graph of the network has a *power-law tail*

- suggests a **scale-free network**
 - ◆ few *hubs* (highly connected)
 - ◆ many nodes with low connectivity
 - ◆ 5% of nodes (major hubs) account for ~ 50.000 connections
 - ◆ hierarchical structure: hubs tend to communicate a lot among each other

Zooming in: MYC subnetwork

- Reverse engineering

Association networks

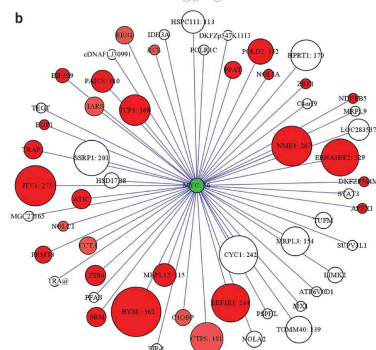

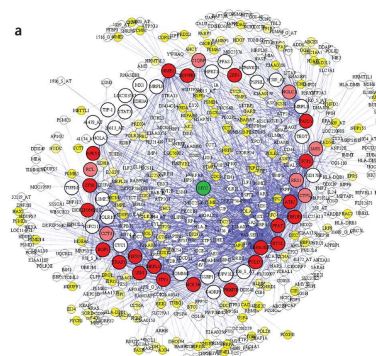

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available

● Results

- MYC subnetwork
- Discussion & Limitations

Linear ODEs networks

- the proto-oncogen MYC is known to be an “important node”
- the algorithm confirmed it as a major hub
 - ◆ 56 first neighbors,
 - ◆ 2007 second neighbors

- 30% of first neighbors are large hubs
- hierarchical structure
- redundancy
- robustness

Validation of the MYC subnetwork

- Reverse engineering

Association networks

- Pearson Correlation
- Mutual information
- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- —NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results

● MYC subnetwork

- Discussion & Limitations

Linear ODEs networks

- 29 out of 56 first neighbors were known MYC targets
- known targets are more significant classified as first neighbors (51.8%) than second neighbors (19.4%)
- 37.5% of first neighbors were validated *in vivo* by chromatin immunoprecipitation (ChIP)
 - ⇒ binding of MYC to their promoter region was shown in new candidate MYC target
 - ⇒ validation *in vivo* of the regulatory pathways

Discussion & Limitations

- Reverse engineering

- Partial Pearson correlation
- Conditional mutual information
- Higher order conditioning
- Algorithms evaluation
- —NETWORKS FOR HUMAN B CELLS
- ARACNe: the algorithm
- Data available
- Results

● MYC subnetwork

- Discussion & Limitations

Linear ODEs networks

- on the positive side:
 - ◆ results are validated experimentally (remarkable)
 - ◆ large part (40%) of the data collected on a decade on MYC was correctly represented
- limitations (in the paper):
 - ◆ edges lack directionality (i.e., they do not indicate which gene is 'upstream' or 'downstream');
 - ◆ some direct connections may involve unknown intermediates, as not all biochemical species participating in cellular interactions are represented on the microarray
 - ◆ some direct interactions may have been incorrectly removed by the DPI
- futher limitations (in my biased opinion)
 - ◆ the # of gene expression profiles they start with is probably too limited
 - ◆ we do not find the DPI very effective

Linear ODEs networks

Linear ODEs networks

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

Parameters fitting

- how do you fit the parameters in a model in order to match experimental data?
 - ◆ → **linear regression analysis**
 - ◆ simplest case: want to fit a straight line to a set of measured values $(x_1, y_1), (x_2, y_2), \dots, (x_m, y_m)$

Parameters fitting

● Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

■ model to fit

$$y = \alpha + \beta x + \epsilon$$

- ◆ α, β regression coefficients
- ◆ y = response, x = regressor
- ◆ $\epsilon \in N(0, \sigma^2)$ random error

■ task: estimate α and β from the measured data $\implies \hat{\alpha}, \hat{\beta}$

■ solution: least squares

observed y = fitted y + residuals

- ◆ fitted y : reflects the straight line $\hat{y} = \hat{\alpha} + \hat{\beta}x$
- ◆ residuals: random deviation from the straight line

$$\begin{aligned} \min_{\hat{\alpha}, \hat{\beta}} S &= \sum_{i=1}^m (\text{observed } y - \text{fitted } y)^2 \\ &= \sum_{i=1}^m (y_i - \hat{\alpha} - \hat{\beta}x_i)^2 \end{aligned}$$

Parameters fitting

● Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

■ $\hat{\alpha}, \hat{\beta}$ can be computed explicitly from the partial derivatives

$$\left. \begin{aligned} \frac{\partial S}{\partial \hat{\alpha}} &= -2 \sum_{i=1}^m (y_i - \hat{\alpha} - \hat{\beta}x_i) = 0 \\ \frac{\partial S}{\partial \hat{\beta}} &= -2 \sum_{i=1}^m x_i (y_i - \hat{\alpha} - \hat{\beta}x_i) = 0 \end{aligned} \right\} \implies \begin{cases} \hat{\beta} = \frac{\sum_{i=1}^m x_i (y_i - \bar{y})}{\sum_{i=1}^m x_i (x_i - \bar{x})} \\ \hat{\alpha} = \bar{y} - \hat{\beta}\bar{x} \end{cases}$$

where $\bar{x} = \frac{1}{m} \sum_{i=1}^m x_i$ and $\bar{y} = \frac{1}{m} \sum_{i=1}^m y_i$ (averages)

■ meaning of the fitted

model $\hat{y} = \hat{\alpha} + \hat{\beta}x$:
line passing through the centroid (\bar{x}, \bar{y}) and rotated until the squared deviations is least.

- ◆ in Matlab:
 - lsqr function
 - regression function (Statistics toolbox)

Least squares fitting of nonlinear models

● Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

■ this to fit a straight line: How about fitting a more complicated curve?

■ linear regression: **linear in the coefficients** α, β , etc., not in the model structure

◆ example: quadratic model

$$y = \alpha + \beta_1 x + \beta_2 x^2 + \epsilon$$

is solvable directly by means of linear regression

■ how about **nonlinear regression**?

Least squares fitting of nonlinear models

● Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

■ example: Maltus law $x(t) = x_0 e^{-\gamma t}$

◆ recall that this is the integral of the linear ODE $\frac{dx}{dt} = -\gamma x$ and describes for example the degradation of a substance

◆ least square fitting: assume I measure a few time values

$$x(t_1) = x_1, \dots, x(t_m) = x_m$$

◆ how do I find γ ?

◆ take the logarithm on both sides of $x(t) = x_0 e^{-\gamma t}$:

$$\underbrace{\ln x(t)}_{y(t)} = \underbrace{\ln x_0}_{\alpha} - \gamma t$$

⇒ linear regression

■ alternatively: measure $x(t)$ and $\frac{dx}{dt}$ simultaneously and fit directly on the ODE

Least squares fitting of nonlinear models

● Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting

- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- how about a Hill function? $h^+(x, \theta, n) = \frac{x^n}{\theta^n + x^n}$
 - ◆ consider $\frac{dx}{dt} = kh^+(x, \theta, n)$
 - ◆ assume x and $\frac{dx}{dt}$ are measured
 - ◆ $k = \text{value at saturation} \implies \text{known from } \frac{dx}{dt} \text{ as } t \rightarrow \infty$
 - ◆ to find θ and n

- manipulating: $\dot{x} = \frac{kx^n}{\theta^n + x^n} \implies x^n = \frac{\dot{x} \theta^n}{k - \dot{x}}$

- take the logarithm

$$\ln(x^n) = \ln\left(\frac{\dot{x} \theta^n}{k - \dot{x}}\right) = \ln\left(\frac{\dot{x}}{k - \dot{x}}\right) + \ln(\theta^n)$$

- i.e.,

$$\underbrace{n}_{\beta} \underbrace{\ln(x)}_x = \underbrace{n \ln \theta}_{\alpha} + \underbrace{\ln\left(\frac{\dot{x}}{k - \dot{x}}\right)}_y$$

\implies linear regression applies

Multiple linear regression

- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- when is $(\mathbf{X}^T \mathbf{X})^{-1}$ well-defined?

$$\mathbf{X} = \begin{bmatrix} 1 & x_1^1 & \dots & x_n^1 \\ 1 & x_1^2 & \dots & x_n^2 \\ \vdots & \vdots & & \vdots \\ 1 & x_1^m & \dots & x_n^m \end{bmatrix}, \quad \begin{array}{l} \mathbf{X} \quad m \times (n+1) \text{ matrix} \\ \mathbf{X}^T \mathbf{X} \quad (n+1) \times (n+1) \text{ matrix} \end{array}$$

- if $\text{rank}(\mathbf{X}^T \mathbf{X}) = n + 1$ then $(\mathbf{X}^T \mathbf{X})^{-1}$ exists

- meaning:

1. $m \geq n + 1$
2. the regressors of \mathbf{X} (i.e., the columns of \mathbf{X}) must be linearly independent

- practical meaning

1. # of experiments must be \geq # of variables
2. data must be collected in different experimental situations

Nonlinear Multiple regression

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- how about nonlinear models?

$$\frac{dx}{dt} = \mathbf{f}(\mathbf{x}, \beta), \quad \mathbf{f}(\mathbf{x}, \beta) = \begin{bmatrix} f_1(\mathbf{x}, \beta) \\ \vdots \\ f_n(\mathbf{x}, \beta) \end{bmatrix}$$

- if $\mathbf{f}(\mathbf{x}, \beta)$ is “diagonal”

$$\mathbf{f}(\mathbf{x}, \beta) = \begin{bmatrix} f_1(x_1, \beta) \\ \vdots \\ f_n(x_n, \beta) \end{bmatrix}$$

then the ODEs are not coupled

⇒ each nonlinear problem can be treated separately

- if not, then there is no general rule to deal with it. A common approach is to linearize around an equilibrium point.

Inferring a network of ODEs

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- network of n genes x_1, x_2, \dots, x_n
- vector ODEs in general form

$$\frac{dx}{dt} = \mathbf{f}(\mathbf{x}), \quad \mathbf{f}(\mathbf{x}) = \begin{bmatrix} f_1(\mathbf{x}) \\ \vdots \\ f_n(\mathbf{x}) \end{bmatrix}$$

$f_i(\mathbf{x})$ = description of how the expression levels of genes x_1, \dots, x_n are affecting the transcription rate of x_i

- typically
 - ◆ $f_i(\mathbf{x}) > 0$ (*activation*) for some combination of x_1, \dots, x_n
 - ◆ $f_i(\mathbf{x}) < 0$ (*repression*) for some other combination
 - ◆ for (x_1, \dots, x_n) such that $f_i(\mathbf{x}) = 0$ for all $i = 1, \dots, n$ then we have a steady state (rate of all x_i stays constant)
- Inferring the network means finding the functions f_i

Inferring a network of ODEs

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- **Inferring a network of ODEs**
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- simplest form: linear model $\frac{dx_i}{dt} = f_i(\mathbf{x}) = a_{i1}x_1 + \dots + a_{in}x_n$

$$\frac{d\mathbf{x}}{dt} = A\mathbf{x}, \quad A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & & a_{2n} \\ \vdots & & \ddots & \vdots \\ a_{n1} & \dots & & a_{nn} \end{bmatrix}$$

- ◆ a_{ij} measure of the interaction strength of gene j over gene i
- ◆ $a_{ij} = 0 \implies$ gene j is not affecting the transcription rate of gene i
- finding A means finding the **connectivity matrix** of the network (i.e., its topology)
- in addition, the a_{ij} also **quantify** the network of connections
- typically only a few a_{ij} are $\neq 0$ on each row \implies low connectivity (the matrix A is **sparse**)

- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- compute the eigenvalues of A
eigenvalues of A = real or complex numbers λ such that $A\mathbf{v} = \lambda\mathbf{v}$ for some vector \mathbf{v} (called *eigenvector*): they give the *characteristic modes* of the ODE $\frac{d\mathbf{x}}{dt} = A\mathbf{x}$
- A is **stable** $\iff \text{Re}[\lambda] < 0$ ($\text{Re}[\lambda] \leq 0$ and multiplicity(λ) ≤ 1)
 - ◆ \implies all modes are decaying
 - ◆ $\implies \mathbf{x}(t) \xrightarrow{t \rightarrow \infty} \mathbf{x}^*$ stable stationary steady state
 - ◆ \implies if I disturb the initial condition: $\mathbf{x}(t) + \delta\mathbf{x}(t) \xrightarrow{t \rightarrow \infty} \mathbf{x}^*$
- if $\text{Re}[\lambda] > 0$ for some eigenvalue $\lambda \implies A$ is **unstable** and $\mathbf{x}(t)$ may grow unbounded

- λ complex number $\implies \mathbf{x}(t)$ has **oscillations**

- $a_{ii} =$ **self-regulating coefficient**: includes degradation rate

$$A = \tilde{A} - \begin{bmatrix} \gamma_1 & & \\ & \ddots & \\ & & \gamma_n \end{bmatrix}$$

- Linearization
- Information extrapolated from A
- **Inferring linear ODEs**
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

$$\dot{X} = AX + B$$

- \Rightarrow finding A becomes a multilinear regression problem

$$A = \operatorname{argmin} \|AX + B - \dot{X}\|_2$$

(i.e., for each row a of A : $\hat{a}^T = (XX^T)^{-1} X(\dot{x}_{\text{row}}^T - b_{\text{row}}^T)$)

- properties
 - ◆ perturbations need not form a diagonal matrix B : all is needed is a matrix X such that $\operatorname{rank}(X) \geq n$ i.e., at least n arrays of “independent” measurements
 - ◆ drawback: A is very sensitive to noise in X and B
 - ◆ drawback: need to measure the rates $\frac{dx}{dt} \rightarrow$ this is normally done by finite difference schemes + interpolation/smoothing provided you have a **time series** of data

Continuous vs Discrete time

- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

■ how to get A out of F ?

1. exact caculation: matrix logarithm

$$A = \frac{\ln(F)}{T}$$

◆ complication: $m < n$

$\implies F$ is not full-rank \implies cannot take log

2. approximation 1.: Euler discretization

$$\frac{dx}{dt} \simeq \frac{x((k+1)T) - x(kT)}{T} \implies x((k+1)T) = (I + TA)x(kT) = Fx(kT)$$

$$A = \frac{F - I}{T}$$

3. approximation 2.: bilinear approximation

$$A = \frac{2F - I}{TF + I}$$

■ both approximations are inadequate when T is not very small

- steady state inference
- model-based drug design

- 9 genes, 9 perturbations \implies enough to compute

$$A = \operatorname{argmin} \|AX + B\|_2$$

although result will be very noisy

- in general however $m \ll n \implies$ underdetermined problem
- instead of using SVD, assume **degree of connectivity** is $k \simeq m$ (meaning: each row of A has at most k nonzero elements)
 - \implies conditioning is better in presence of a limited number of experiments
- solution is still Moore-Penrose pseudoinverse
- drawbacks of the method
 - to find the "best" row of k parameters a_{ij} is a combinatorial problem: $\frac{n!}{k!(n-k)!}$ (" n choose k ")
 - \implies computational explosion
 - \implies heuristic solutions

What lies ahead? Model-based drug design

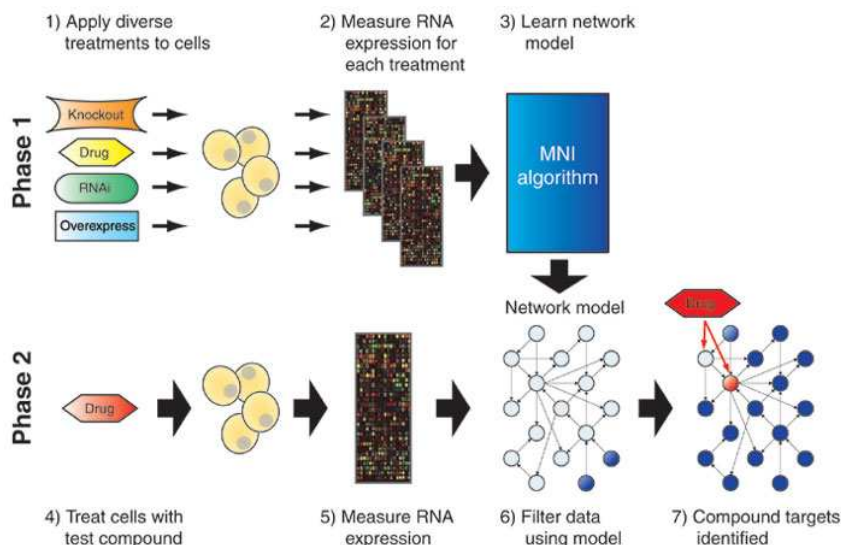

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from Δ
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

di Bernardo D, Thompson MJ, Gardner TS, Chobot SE, Eastwood EL, Wojtovich AP, Elliott SJ, Schaus SE, Collins JJ. *Chemogenomic profiling on a genome-wide scale using reverse-engineered gene networks* Nat Biotechnol. 2005 ,23(3):377-83

What lies ahead? Model-based drug design

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- assume to have identified the matrix A in

$$\dot{x} = Ax$$

- assume you want to test the effect of an external stimulus u (e.g. drug) on the system

- **task:** compute the mode of action of u :
 - ◆ applying u to the linear system

$$\dot{x} = Ax + bu$$

- ◆ $b = n \times 1$ vector of coefficients = pathways through which the drug is acting → directly regulated genes
- ◆ all indirect regulations must be obtained from A
 - ⇒ fundamental prerequisite: have a sound knowledge of A
- ◆ finding b is easier than finding A (similar procedure)

What lies ahead? Model-based drug design

- Reverse engineering

Association networks

Linear ODEs networks

- Nonlinear Fitting
- Multiple linear regression
- Nonlinear Multiple regression
- Inferring a network of ODEs
- Linearization
- Information extrapolated from A
- Inferring linear ODEs
- Continuous vs Discrete time
- Inferring a linear model via SVD
- steady state inference
- model-based drug design

- **task:** compute time-dependent $u(t)$ such that

$$x(t) \rightarrow x_{\text{desired}}$$

- x_{desired} = particular array of expression levels of the genes of the system that I would like to achieve
- model can tell you when this is possible / not possible for a certain u or a linear combination of u s:

$$\dot{x} = Ax + [b_1 \dots b_p] \begin{bmatrix} u_1 \\ \vdots \\ u_p \end{bmatrix}$$

→ linear (or nonlinear) control theory?
